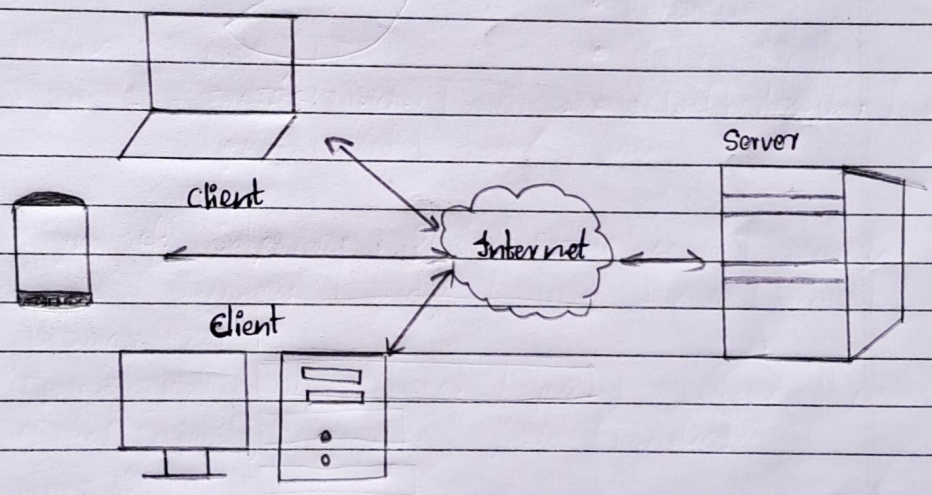
Assignment - Internet Explorer

Client - Server Architecture

Client - server architecture is a way computers communicate over the internet. Client send requests for the resources or services, and servers process these requests, returning the required responses.

- The client is the user's device that requests information.
- The server is a powerful computer that stores websites, data and applications.
- Network is the communication medium that enables data exchange using protocols like HTTP/HTTPS, TCP/IP, or SMTP.

This model helps manage data centrally, improves security, and allows many users to access the same service at the same time.



What happens when we open a website:

1. The user types the website address in web browser.
2. The browser sends a request to the internet to access the website.
3. The DNS converts the website's name into its IP address.
4. The request reaches the web server where the website is stored.

5. The server processes the request and resources searches for the required files.
6. The server sends back the response containing HTML, CSS, JavaScript and images.
7. The browser reads those files and displays the website on the screen.
